CONSENT FOR TESTING PROCEDURE

Thermal imaging of the breasts, otherwise known as breast thermography, uses a specialised infrared camera to precisely measure breast temperature at high resolution. From these images, a trained thermographic specialist can pinpoint and identify temperature anomalies which indicate potential problems or risk. Thermography does not diagnose cancer or rule out its presence but does point out breast health problems (cancer being the most common) that the patient should follow up with their health care provider. Thermography does not replace other breast screening procedures but it has proven to be an effective tool in the early detection of breast health problems and with no discomfort or health risk to the patient.

I have read and complied with the pre-examination instructions for an accurate thermographic screening and hereby authorise InfraMed's personnel to proceed with the thermographic examination.
